## 1 Introduction

`sp` (Pebesma & Bivand, 2005) is an important package that defines standards and allows for exchanging information between spatial packages in R. As `aRT` manipulates all spatial data formats, it was designed to follow `sp` standards to represent spatial data, storing and retrieving data using the `sp` format. Therefore, when working with `aRT` and spatial data in R it is required that objects containing spatial data are converted, whenever necessary, to the `sp` format. For further details on `sp` package see <http://r-spatial.sourceforge.net>.

On the other hand, `TerraLib` databases can contain data that cannot be directly converted to `sp` data. For example:

1. `TerraLib` (and therefore `aRT`) requires ID in *all* spatial data, different from `sp`, that requires ID only for lines and polygons.

2. TerraLib layers have support to multigeometry, meaning that each spatial element can have more than one geometry associated. For example, a layer of cities can store both contours and centroids.
3. geometries and attributes are stored in different objects in a TerraLib database. Geometries are stored directly inside layers, whereas attributes are stored in tables inside layers. The reason why tables cannot be in the same object as geometries is because TerraLib supports different table formats, for example *static*, *event*, and *dynamic*.

This document illustrates how to manipulate spatial data in aRT, showing how to import to and read from TerraLib databases. The data (and also some sentences!) of this document are extracted from Pebesma and Bivand (2005).

We start by loading the package and, for convenience here, setting aRT to the silent mode which hides some information messages issued by aRT functions; followed by establishing a connection to a DBMS. The database to be used in the examples is called “sp”, which, if exists, is removed from the DBMS and recreated. Notice this is a TerraLibdatabase, i.e., a database created following the TerraLib structure.

```
> require(aRT)
> aRTsilent(TRUE) # hiding info messages

[1] TRUE

> con = openConn(name="default")
> if(any(showDbs(con)=="sp")) deleteDb(con, "sp", force=T)
> db = createDb(con, "sp")
```

Further details on connections to the DBMS are provided by the vignette *aRTconn*.

## 2 Spatial points

### 2.1 Points without attributes

Our first example illustrates how to handle data with a *points geometry*. For instance, consider a set of 10 points randomly generated on the unit square  $[0, 1] \times [0, 1]$  and stored in a matrix *xy*. The first step is to use *sp* to convert into a *SpatialPoints* object.

```
> xy = matrix(runif(20), nc=2)
> xy.sp = SpatialPoints(xy)
> xy.sp
```

```
SpatialPoints:
      coords.x1 coords.x2
[1,] 0.6739453 0.3021973
```

```

[2,] 0.9619853 0.6170330
[3,] 0.9228386 0.9050982
[4,] 0.7747456 0.8476483
[5,] 0.7248062 0.4579902
[6,] 0.7413480 0.3863993
[7,] 0.6302933 0.6443511
[8,] 0.1903071 0.7170724
[9,] 0.6977443 0.1980982
[10,] 0.3703263 0.2772779
Coordinate Reference System (CRS) arguments: NA

```

However, an `SpatialPoints` object cannot be used by `aRT` functions because it does not have ID and it is necessary to convert to a `SpatialPointsDataFrame`.

```
> xy.spdf = SpatialPointsDataFrame(xy, data.frame(ID=paste(1:10)))
```

Note that here you can use both `xy` or `xy.spdf` as argument to `SpatialPointsDataFrame`.

The first step to store this data in a TerraLib database is to create a *layer*. A layer is a container that can store any geometric type and also, optionally, other types of objects. A layer can be created in a database using `createLayer()` and the function call receives as arguments the database object and a string defining the name to be set for the layer.

```
> lpoints = createLayer(db, "points")
> lpoints
```

Object of class `aRTlayer`

```

Layer: "points"
Database: "sp"
Layer is empty
Projection Name: "NoProjection"
Projection Datum: "Spherical"
Tables: (none)

```

Notice that we have two names, `"points"` which is the name of the layer in the database, and `lpoints`, an R object which can access `"points"`. Next the function `addPoints()` is used to store the points into the layer. Notice that after that the layer object acknowledges the points are now stored into the database.

```
> addPoints(lpoints, xy.spdf)
> lpoints
```

Object of class `aRTlayer`

```

Layer: "points"
Database: "sp"

```

```
Number of points: 10
Projection Name: "NoProjection"
Projection Datum: "Spherical"
Tables: (none)
```

To conclude storing the points a further step creating adding a table to the layer is still necessary in order to be able to read any data from the layer. This is a TerraLib requirement needed even when the spatial data does not have any attributes. Geometries with no entry in any table cannot be retrieved from the database.

```
> tpoints = createTable(lpoints, "tpoints")
> tpoints
```

Object of class `aRTtable`

```
Table: "tpoints"
Type: static
Layer: "points"
Rows: 10
Attributes:
  id: character[16] (key)
```

```
> lpoints
```

Object of class `aRTlayer`

```
Layer: "points"
Database: "sp"
Number of points: 10
Projection Name: "NoProjection"
Projection Datum: "Spherical"
Tables:
  "tpoints": static
```

Now the layer has 10 points and one table, and we can retrieve the point coordinates using `getPoints()`, which returns an object of class `SpatialPoints-DataFrame`:

```
> points = getPoints(lpoints)
> points
```

```
      coordinates ID
1 (0.673945, 0.302197) 1
2 (0.370326, 0.277278) 10
3 (0.961985, 0.617033) 2
4 (0.922839, 0.905098) 3
5 (0.774746, 0.847648) 4
```

```

6 (0.724806, 0.45799) 5
7 (0.741348, 0.386399) 6
8 (0.630293, 0.644351) 7
9 (0.190307, 0.717072) 8
10 (0.697744, 0.198098) 9

```

Note that the points have a different order from the original data. That is because the database stores the IDs as characters, therefore 10 comes before 2.

Figure 2 illustrates two different ways for visualising the point coordinates, on the left by plotting the points from an R object with `plot(points)`, or directly from the layer, with `plot(lpoints)`, which does not requires the existence of an R object containing the points.

Figure 1: Plot of a layer with points

## 2.2 Points with attributes

Another possible way of creating a `SpatialPointsDataFrame` object is by building it by combining a `SpatialPoints` object and a data frame containing associated attributes. In the following example we combine the object `xy.sp` with

a data frame `df` containing attributes. Notice the ID column is required by any `sp` object.

```
> df = data.frame(z1 = round(5 + rnorm(10), 2), z2 = 0:9, ID = paste(1:10))
> xy.spdf = SpatialPointsDataFrame(xy.sp, df)
> xy.spdf
```

```
          coordinates    z1 z2 ID
1 (0.673945, 0.302197) 3.10 0 1
2 (0.961985, 0.617033) 4.15 1 2
3 (0.922839, 0.905098) 3.68 2 3
4 (0.774746, 0.847648) 4.45 3 4
5 (0.724806, 0.45799) 6.62 4 5
6 (0.741348, 0.386399) 5.57 5 6
7 (0.630293, 0.644351) 3.66 6 7
8 (0.190307, 0.717072) 3.75 7 8
9 (0.697744, 0.198098) 5.19 8 9
10 (0.370326, 0.277278) 5.02 9 10
```

As before we create a layer and add the points to it. Next, as our object now has attributes, we can import the table data using `importTable()`.

```
> lpoint sdf = createLayer(db, "lpoint sdf")
> addPoints(lpoint sdf, xy.spdf)
> tpoint sdf = importTable(lpoint sdf, "tpoint sdf", ID="ID", xy.spdf)
> tpoint sdf
```

Object of class `aRTtable`

```
Table: "tpoint sdf"
Type: static
Layer: "lpoint sdf"
Rows: 10
Attributes:
  id: character[16] (key)
  z1: numeric
  z2: integer
```

```
> lpoint sdf
```

Object of class `aRTlayer`

```
Layer: "lpoint sdf"
Database: "sp"
Number of points: 10
Projection Name: "NoProjection"
Projection Datum: "Spherical"
Tables:
  "tpoint sdf": static
```

When retrieving data from the database to R getting point coordinates and the table at once from the layer we can use a second argument of `getPoints()` with the table to be read.

```
> getPoints(lpointsdf, tpointsdf)

      coordinates ID  z1 z2
1 (0.673945, 0.302197) 1 3.10 0
2 (0.370326, 0.277278) 10 5.02 9
3 (0.961985, 0.617033) 2 4.15 1
4 (0.922839, 0.905098) 3 3.68 2
5 (0.774746, 0.847648) 4 4.45 3
6 (0.724806, 0.45799) 5 6.62 4
7 (0.741348, 0.386399) 6 5.57 5
8 (0.630293, 0.644351) 7 3.66 6
9 (0.190307, 0.717072) 8 3.75 7
10 (0.697744, 0.198098) 9 5.19 8
```

## 2.3 Doing all at once

All the steps above can be encapsulated using `importSpData()`.

## 3 Grids

(not supported yet)

## 4 Lines

### 4.1 Building line objects from scratch

In many instances, line coordinates will be retrieved from external sources. The following example shows how to build an object of class `SpatialLines` from scratch. As objects from this class already stores ID, they are pushed in the layer directly using `addLines()`.

```
> l1 = cbind(c(1,2,3),c(3,2,2))
> l1a = cbind(l1[,1]+.05,l1[,2]+.05)
> l2 = cbind(c(1,2,3),c(1,1.5,1))
> S11 = Line(l1)
> S11a = Line(l1a)
> S12 = Line(l2)
> #S1 = Lines(list(S11, S11a), ID="a")
> S1 = Lines(list(S11), ID="a")
> S2 = Lines(list(S12), ID="b")
> S3 = Lines(list(S11a), ID="c")
> S1 = SpatialLines(list(S1,S2,S3))
```

```
> llines = createLayer(db,"llines")
> addLines(llines, S1)
> createTable(llines, "llines")
```

Object of class aRTtable

```
Table: "llines"
Type: static
Layer: "llines"
Rows: 3
Attributes:
  id: character[16] (key)
```

Figure 2: Plot of a layer with lines

## 4.2 Building line objects with attributes

The same as polygons

## 5 Polygons

### 5.1 Building from scratch

The following example shows how a set of polygons are built from scratch. Note that `Sr4` has the opposite direction (right) as the other three; it is meant to represent a hole in the `Sr3` polygon.

```
> #genPol = function(quant)
> #{
> #   res = list()
> #   res = lapply(1:quant, function(x) {
> #     from = round(runif(2,1,20),2)
> #     to   = from + round(runif(2,1,5),2)
> #
> #     Sr1 = Polygon(cbind(c(from[1],from[1],to[1],to[1], from[1]),
> #                         c(from[2],to[2], to[2],from[2],from[2])))
> #     Srs1 = Polygons(list(Sr1),paste(x))
> #   })
> #   SR = SpatialPolygons(res, 1:quant)
> #}
>
> Sr1 = Polygon(cbind(c(2,4,4,1,2),c(2,3,5,4,2)))
> Sr2 = Polygon(cbind(c(5,4,2,5),c(2,3,2,2)))
> Sr3 = Polygon(cbind(c(4,4,5,10,4),c(5,3,2,5,5)))
> Sr4 = Polygon(cbind(c(5,6,6,5,5),c(4,4,3,3,4)), hole = TRUE)
> Srs1 = Polygons(list(Sr1), "s1")
> Srs2 = Polygons(list(Sr2), "s2")
> Srs3 = Polygons(list(Sr3, Sr4), "s3/4")
> SR = SpatialPolygons(list(Srs1,Srs2,Srs3), 1:3)
> lrings = createLayer(db, "lrings")
> addPolygons(lrings, SR)
> trings = createTable(lrings, "trings")
> #th=createTheme(lrings, "trings")
> lrings

Object of class aRTlayer

Layer: "lrings"
Database: "sp"
Number of polygons: 4
Projection Name: "NoProjection"
Projection Datum: "Spherical"
Tables:
  "trings": static

> #sr = as.SpatialPolygon(getGeometry(lrings))
>
```

Figure 3: plot of a layer with polygons

```
> polys = getPolygons(lrings)
```

## 5.2 Polygons with attributes

Polygons with attributes, objects of class `SpatialPolygonsDataFrame`, are built from the `SpatialPolygons` object (topology) and the attributes (data.frame):

```
> #attr = data.frame(a=1:3, b=3:1, row.names=c("s1","s2","s3/4"))
> #SrDf = SpatialPolygonsDataFrame(SR, attr)
> #lringsdf = createLayer(db, "lringsdf")
> #addPolygons(lringsdf, SrDf)
```

To import the attributes, we need to create a table, but, due to the internal differences of `sp` data storage

```
> #xy.spdf@data
> #SrDf@data
> #class(SrDf@data)
```

we need to insert `SrDf` manually, creating both table and the two integer columns before inserting the data:

```
> #tringsdf = createTable(lringsdf, "tringsdf", ID="ID", gen=F)
> #createColumn(tringsdf, "a", "i")
> #createColumn(tringsdf, "b", "i")
> #addRows(tringsdf, SrDf@data)
> #tringsdf
> #lringsdf
>
> #getData(tringsdf)
>
> #sr = as.SpatialPolygons(getGeometry(lringsdf))
> #summary(sr)
> #sr = as.SpatialPolygonsDataFrame(getGeometry(lringsdf))
> #sr
```
